Likelihood Ratio / Score Function Policy Gradient

$$\nabla_{\theta} V(\theta) = \frac{1}{m} \sum_{i=1}^{m} R(\tau^{(i)}) \sum_{t=0}^{T-1} \nabla_{\theta} \log \pi_{\theta}(a_{t}^{(i)} \mid s_{t}^{(i)})$$

- Unbiased but very noise
- Fixes that can make it practical
 - ▶ Temporal structure
 - Baseline
 - (and some more)

Policy Gradient: Use Temporal Structure

$$\nabla_{\theta} \mathbb{E}_{\tau}[R] = \mathbb{E}_{\tau} \left[\left(\sum_{t=0}^{T-1} r_t \right) \left(\sum_{t=0}^{T-1} \nabla_{\theta} \log \pi_{\theta}(a_t \mid s_t) \right) \right]$$

We can repeat the same argument to derive the gradient estimator for a single reward term r_{t^\prime}

$$\nabla_{\theta} \mathbb{E}[r_{t'}] = \mathbb{E}\left[r_{t'} \sum_{t=0}^{t'} \nabla_{\theta} \log \pi_{\theta}(a_t \mid s_t)\right]$$

Summing this formula over t, we obtain:

$$V(\theta) = \nabla_{\theta} \mathbb{E}[R] = \left[\sum_{t'=0}^{T-1} r_{t'} \sum_{t=0}^{t'} \nabla_{\theta} \log \pi_{\theta}(a_t \mid s_t) \right]$$
$$= \left[\sum_{t=0}^{T-1} \nabla_{\theta} \log \pi_{\theta}(a_t \mid s_t) \sum_{t=t}^{T-1} r_{t'} \right]$$

Policy Gradient: Use Temporal Structure

 \bullet Recall for a particular trajectory $\tau^{(i)}$, $\sum_{t'=t}^{T-1} r_{t'}^{(i)}$ is the return $G_t^{(i)}$

$$\nabla_{\theta} \mathbb{E}[R] \approx \frac{1}{m} \sum_{t=1}^{m} \sum_{t=0}^{T-1} \nabla_{\theta} \log \pi_{\theta}(a_t, s_t) G_t^{(i)}$$

Monte-Carlo Policy Gradient (REINFORCE)

Leverages likelihood ratio / score function and temporal structure

$$\Delta \theta_t = \alpha \nabla_\theta \log \pi_\theta(s_t, a_t) G_t$$

REINFORCE:

- **1** Initialize policy parameters θ arbitrarily
- **2** for each episode $\{s_1, a_1, r_2, \dots, s_{T-1}, a_{T-1}, r_T\} \sim \pi_{\theta}$ do
 - for t = 1 to T 1 do

$$\star \theta := \theta + \alpha \nabla_{\theta} \log \pi_{\theta}(s_t, a_t) G_t$$

 \odot return θ

Policy Gradient: Introduce Baseline

• Reduce variance by introducing a baseline b(s)

$$\nabla_{\theta} \mathbb{E}_{\tau}[R] = \mathbb{E}_{\tau} \left[\sum_{t=0}^{T-1} \nabla_{\theta} \log \pi(a_t \mid s_t; \theta) \left(\sum_{t'=t}^{T-1} r_{t'} - b(s_t) \right) \right]$$

- For any choice of b, gradient estimator is unbiased
- Near optimal choice is the expected return

$$b(s_t) \approx \mathbb{E}[r_t + r_{t+1} + \ldots + t_{T-1}]$$

• Interpretation: increase logprob of action a_t proportionally to how much returns $\sum_{t'=t}^{T-1} r_{t'}$ are better than expected

"Vanilla" Policy Gradient Algorithm

- ullet Initialize policy parameters heta and baseline b
- for iteration $= 1, 2, \dots$ do
 - Collect a set of trajectories by executing the current policy
 - At each timestep t in each trajectory τ^i , compute
 - ***** Return $G_t^i = \sum_{t'=t}^{T-1} r_{t'}^i$ and
 - ★ Advantage estimate $\hat{A}_t^i = G_t^i b(s_t)$
 - ▶ Re-fit the baseline by minimizing $\sum_i \sum_t ||b(s_t) G_t^i||^2$
 - Update the policy, using a policy gradient estimate \hat{g}
 - * which is a sum of terms $\nabla_{\theta} \log \pi(a_t \mid s_t; \theta) \hat{A}_t$
 - ★ Apply gradient \hat{g} by any DL-optimizer (e.g., SGD or ADAM)

Choosing the Baseline: Value Functions

• Recall Q-function:

$$Q^{\pi}(s,a) = \mathbb{E}_{\pi}[r_0 + \gamma r_1 + \gamma^2 r_2 + \dots \mid s_0 = s, a_0 = a]$$

State-value function can serve as a great baseline

$$V^{\pi}(s) = \mathbb{E}_{\pi}[r_0 + \gamma r_1 + \gamma^2 r_2 + \dots \mid s_0 = s]$$

= $\mathbb{E}_{a \sim \pi}[Q^{\pi}(s, a)]$

• Advantage function: Combining Q with baseline V:

$$A^{\pi}(s,a) = Q^{\pi}(s,a) - V^{\pi}(s)$$
